Judges' guide, one page

Live app: https://zishi-fintechathon.vercel.app. English and Simplified Chinese (toggle in the top bar), light and dark. Nothing to install, no wallet to connect.

1. Ten minutes, in order

Minute	Where	What you see
0 to 1	Home	The drone, the lender, the farmer, the two bonds, in one screen. The idiom 自食其力: to feed yourself by your own labour
1 to 4	Dashboard, press Start	The five moments: a job declined on economics, a paid flight with the fee split, a faked flight log held, a compromised intent slashed by proof, the title moving to the pilot at zero
4 to 6	Live	A seeded feed of new jobs every few seconds with the odd injection attempt, or your own jobs as JSON or CSV. Same engine, your data
6 to 9	Evidence	52 attacks run while you watch, the benign set, the naive wallet baseline, ten learned components with held out numbers, the drift monitors, the contracts with explorer links
9 to 10	Repository	`docs/EXECUTION_EVIDENCE.md`: 40 real transactions from one run, every receipt fetched back from Base Sepolia

2. What to click

- **Any transaction hash** in the Dashboard ledger. In simulated mode it is labelled simulated. In real mode it opens Basescan: `IntentLog.commit` calls go to the contract, money events are anchored as calldata on the demo wallet.
- **A policy decision** in the Dashboard. Every rule line is listed with its verdict; the signer is recovered from the EIP-712 signature.
- **The proof receipt** at moment four. The intent hash, the signature check, the rule, which bond paid, who was paid and that no bounty was paid on a live job.
- **Learned components** on the Evidence page. Each card states its seed, its held out split and what it may and may not do (hold, never allow).
- **The judge console** on the Evidence page. Paste any message. You get the gate verdict, what the agent would understand, what the policy engine would decide on the resulting intent, and what a naive wallet would have paid.

3. What to verify

Claim	How
The contracts exist and match the source	Open the four addresses in `contracts/deployments/base-sepolia.json` on Basescan; Sourcify shows an exact match
The engine really calls IntentLog	Open any `IntentLog.commit` row in `docs/EXECUTION_EVIDENCE.md`: the receipt's `to` is the IntentLog address and it carries one `Committed` event
The attack set is run, not pasted	Evidence page, the timestamp next to the attack table changes on reload; `pnpm test` reruns it in CI

Claim	How
The learned numbers are held out	`docs/EVALUATION.md` names the seed and the split for every component; `docs/results/*.json` holds the raw values; `pnpm bench` and `pnpm charts` recompute them
Every money decision is in code	`web/src/engine/policy.ts`: 21 rule lines as data; `web/src/engine/model.ts`: the model writes one sentence and never sees a key or a payee
A run cannot be edited after the fact	`GET /api/replay`: the hash chained log of the last runs and its verification

4. Real mode

The public link runs simulated and says so on every hash, so nobody can spend the demo wallet. Real mode needs a demo token that we hand over with the submission; open the app once with `?demo=<token>` and the browser keeps it. A full real run makes 15 contract calls and about 25 anchors and takes a few minutes because each transaction waits for its receipt.

5. What is real, what is simulated

Real	Simulated
EIP-712 signatures, one key per actor, replay and nonce checks	The farmer, pilot, lender and vendor are scripted; their keys are generated at boot
Four contracts on Base Sepolia, 43 Foundry tests	Bond, JobBoard and Lease rules run in TypeScript mirrors; only IntentLog is called on chain
52 attack cases run at request time	Flight telemetry and the message corpus are synthetic and say so
Hash chained event log, verifiable through the API	Model explanations are templates unless an AI gateway key is set; decisions never depend on the model

6. Documents

File	What it is
`README.md`	The product, the numbers, the architecture, the charts
`TECHNICAL.md`	Architecture, data model, the loop, every rule, every learned component, contracts, chain modes, bring your own data, API, i18n, deployment, testing, security boundaries
`SELF_ASSESSMENT.md`	Security self assessment: risks, what is built, what production would do
`docs/EXECUTION_EVIDENCE.md`	A real run, every receipt fetched back from the chain
`docs/RED_TEAM.md`	The attack set, the benign set and the naive baseline, run at generation time
`docs/EVALUATION.md`, `docs/results/`	Held out results of the ten learned components
`docs/charts/`	Nine charts drawn from the engine
`DESIGN.md`	Product design, economics, the demo story
`contracts/README.md`, `web/README.md`	The contracts and the app
