Demo video script, two and a half minutes

Screen recording of the live app, one voice, light music under the first ten seconds only. Record at 1920 by 1080, English interface, 100 percent zoom. About 380 spoken words.

Before recording: open `zishi-fintechathon.vercel.app/app/live?demo=<token>` once so hashes are real Base Sepolia transactions, check the wallet on Basescan, and open `docs/FISCO_EVIDENCE.md` on GitHub in a second tab.

Time	On screen	Say
0:00	Home page, hero, slow scroll	This drone costs 55,000 yuan. The pilot who flies it has nothing to pledge, so no bank will lend to him. What if the drone could borrow for itself?
0:12	Hero title 自食其力	This is Zishi. A wallet for a machine. It earns per mu sprayed, repays its lender from every fee, and owns itself at zero.
0:22	Fleet page, press Start	Here is one drone, live, on a real blockchain. Every card is a signed intent, a policy decision or a transaction.
0:32	Moment one, the declined job	First job: 20 mu of maize. The planner runs the numbers, the margin is too thin, and the code says no. Signed, logged, declined. Nothing moves.
0:45	Moment two, the fee split, open the instalment card	Next, 100 mu of passion fruit. The farmer confirms, and the fee splits by rule: the lender's instalment, the bond, the pilot's pay. Every transaction is real. Click it, it is on chain.
1:02	Moment three, the held log	Now someone fakes a flight log. The oracle smooths the GPS track, scores it, and holds the money. The lender is told before a yuan leaves.
1:15	Moment four, the slash by proof	Then the AI is compromised and signs a payment to a stranger. The intent was already on chain. A party submits the proof, the contract checks it, and the vendor bond pays. The AI vendor pays for the AI's mistake, not the pilot.
1:35	Moment five, the title card	The last instalment lands. The lease hits zero. The title moves to the pilot. The drone belongs to the person who flew it.
1:45	Evidence page, type an attack in the box	Try to break it. Type any scam. 52 attacks run every time this page loads. 52 blocked. The model holds no key and never decides who gets paid. Code does.
2:00	GitHub tab, docs/FISCO_EVIDENCE.md, scroll the both ledgers table	And it is built on WeBank's stack. The same contracts run on FISCO BCOS, the consortium chain a licensed lender would run. One run, two ledgers: every intent sent to the public chain and to FISCO, same hash, both receipts successful.
2:15	Landing page, WeBank cards	Credit for new pilots is trained across three lenders with FATE, and no lender hands over a record. The model's fingerprint sits on FISCO, so anyone can check which model set the rate.
2:25	Toggle to 中文, then the home page	In English and Chinese. Zishi. Software that lets machines pay for themselves.

If a real transaction is slow, keep talking over the pending state; the pill moves from pending to confirmed to finalised on its own. If the wallet runs dry, use the public simulated mode and say so on camera.
